Class 6 - Elements III: Constructs and variables

Agenda

- Skills corner: DAGs x formal theory (15 minutes)
- Conceptual grounding (5 minutes)
- Core paper discussion (40 minutes)
- *Break*
- Compare-contrast presentation (40 minutes)
- Key thinking tool: Validity assessments (15 minutes)

Skills corner

Switching gears

- Up until now, we have been focused on reading and digesting information from articles
 - Now, we turn to developing your supporting skills for integrating theoretical and empirical models, analyzing and interpreting data, discerning what methods and inferences are appropriate

Key Thinking Tool: DAGs

Directed acyclic graph

has nodes (constructs) and edges (relationships)

there are no loops

the relationships have a direction of influence (correlations are bidirectional)

Key Thinking Tool: DAGs

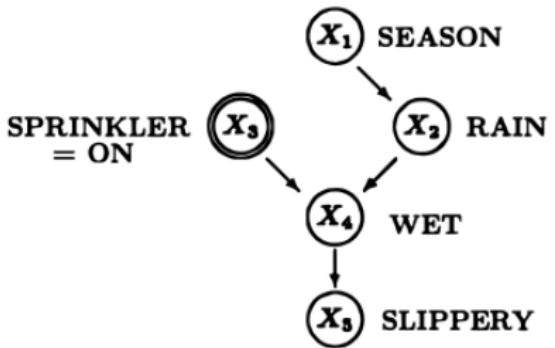

Figure 1.4 Network representation of the action “turning the sprinkler On.”

Figure 1: A Bayesian DAG model courtesy of (Pearl 2001)

Why DAGs?

They provide a visual tool to determine if the claims we make can possibly be causal (Pearl 2010)

They provide a scaffold upon which future researchers can more easily build

And at a minimum, they force us to **write out our model explicitly** in terms of constructs and relationships

Key Thinking Tool: Formal theory

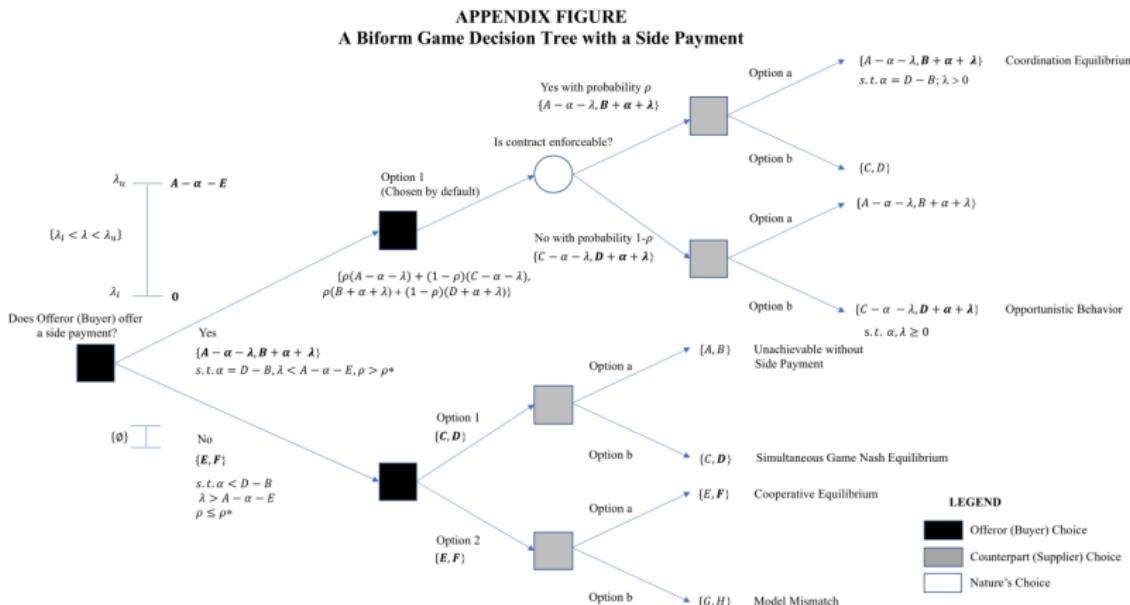

Figure 2: An example analytic model from (Fox, Grove, and Souder 2021)

Why formal theory?

- 1 precision and transparency
- 2 logical consistency, and
- 3 an ability to identify unanticipated implications (Adner et al. 2009, 202)

Integrating DAGs with formal theory

- DAGs can make clear how a model fits within a larger set of nomological networks, be they theoretical or phenomenonological
- Formal theorizing provides the tools to consider more complex relationships and nth-order effects than verbal theorizing readily affords, which tends to capture first-order, linear¹ chains of logic
- Note that the final paper may not showcase this work, but it can be the scaffolding to facilitate deep thinking

¹Note that linearity is not as technically constraining as it may seem. Linearity means that a tested function must be linear with respect to its **parameters**, not its **arguments**. Thus, $y = \beta x^2$ is permissible but $y = \beta^2 x$ is not. The issue is not so much a technical issue but straight-line thinking

2010, Vol. 35, No. 3, 340-357

EDITOR'S COMMENTS: CONSTRUCT CLARITY IN THEORIES OF MANAGEMENT AND ORGANIZATION

One of the most commonly cited reasons for rejecting a manuscript of AMR is that reviewers feel the submitted logic is confused. Yet reviewers often also find it difficult to articulate precisely what construct clarity is. Indeed, in contrast to other social sciences, such as sociology and psychology, where the nature and scope of construct clarity are well understood, the field of management seems unusually silent on the subject. The absence of an operational definition of construct clarity is somewhat surprising given their widespread use and undeniable importance to management theory.

The purpose of this essay, then, is to establish. My first objective is pragmatic: I hope to offer some degree of clarification about how the issue of construct clarity is dealt with at AMR. I do so by offering a definition of construct clarity based on the subject in management journals and in journals from related social science disciplines. Ideally, this will assist authors of prospective AMR manuscripts in understanding the nature of theoretical constructs. My second objective is less pragmatic but, arguably, more important: I hope to open a dialogue within the AMR community about the role and use of constructs in developing theories.

Before doing this, however, I should be clear about the scope of this essay. The intent is not to discuss the concept of construct clarity as a subsidiary topic of high importance that has received and continues to receive considerable attention (i.e., Bograd & Edwards, 1996; Cook & Campbell, 1994; Fornell & Larcker, 1996). Construct clarity and validity are quite distinct (Borchers, 1988). Issues of construct validity, which flows from the ability to employ my previously described theoretical constructs, are more

narrowly constituted on empirical questions of operationalization and measurement.

Nor is my intent to discuss the broader issue of construct clarity in "soft" disciplines. This topic has already received substantial prior, more skilled attention (i.e., Borchers, 1988; Sutton & Staw, 1985; Womack, 1990). While I believe that strong, clear constructs contribute to good theory, my goal here is more modest. I simply intend to focus the discussion on why we need clarity in our theories, the role of constructs in management and how best to accomplish this.

This essay proceeds in four parts. In the first I discuss what constitutes a theoretical construct and how to be more clear about them. In the second, I outline why we need clear constructs in management theory. In the third part I outline how the term construct clarity applies to different kinds of researchers, and I explore how standards of construct clarity vary across epistemological and methodological divisions. Finally, I present a concluding argument about the need for more open dialogue about the role of constructs in our disciplines.

WHAT ARE CONSTRUCTS... AND WHAT IS CONSTRUCT CLARITY?

Constructs are conceptual abstractions of phenomena that cannot be directly observed (MacCannell & Mead, 1989). Karlberg describes a construct as "a concept that has been deliberately and consciously invented or adopted for a special scientific purpose" (1973, p. 2). Constructs are not reducible to specific observable events, but rather are general categories of observation (Prus & Burles, 2000). Clear constructs are simply robust categories that are "comprehensible to a community of researchers—that is, animal, mineral, or vegetable; gas, liquid, or solid."

Constructs are the building blocks of theory. Beckman defines theory as "a 'system of constructs ... in which the constructs are related to each other'" (1987, p. 10).

I thank Bob Gephart, Bob Hastings, Dean Wheless, and the editor and members of the editorial board of the Academy of Management Review for their helpful and stimulating comments on earlier versions of this essay.

Suddaby (2010)

Discussion Questions

- Do you agree with Suddaby's definition of a construct?
- Can you provide an example of a clear construct from your readings? Why is it so?
- How about a construct that is completely unclear? How could we make it better?

Suddaby (2010)

The essence of construct clarity comprises four basic elements (Suddaby 2010, 347).

- Definitions: skillful use of language to persuasively create precise and parsimonious categorical distinctions
- Scope conditions: circumstances under which a construct will or will not apply
- Semantic relationships: how does the construct relate to others
- Coherence: consistency with relation to overall theoretical argument

Larsen and Bong (2016)

Table 1. Construct Identity Fallacy Matrix

		Construct Names	
		Same	Different
Phenomena	Correspondent	Correct outcome: True positive	Jangle fallacy: False negative
	Independent	Jingle fallacy: False positive	Correct outcome: True negative

Larsen and Bong (2016)

Discussion Questions

- What are the jingle / jangle fallacies?
- Have you seen something like this in your work or research to date?

Larsen and Bong (2016)

Key points

- There are tools to help you find and locate constructs
- You can help future research by taking the time to determine whether you need to create a new construct to make your point
- Aside: This paper also is a nice example of weaving quantitative analysis into a literature review by drawing on the sensitivity/specificity framework (TP/FP, TN/FN)

Bagozzi Yi and Phillips (1991)

Figure 1. Illustration of the confirmatory factor analysis model for four traits and two methods applied to the example drawn from Bagozzi & Phillips (1982).

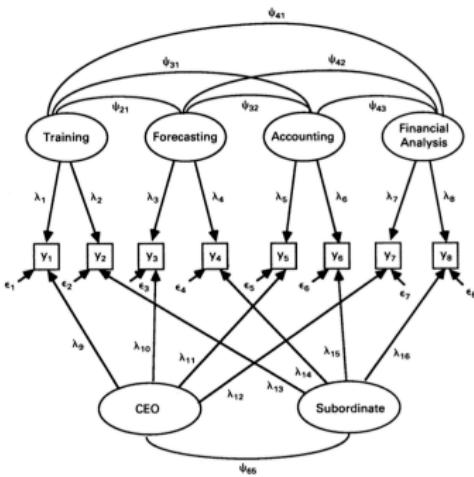

Figure 3: An example of an MTMM-centric CFA

Bagozzi Yi and Phillips (1991)

Discussion questions

- I know this was dense, what did you get out of this paper?
- Based on this paper, how can we demonstrate construct validity?
- Is this logic of all this just circular?

Bagozzi Yi and Phillips (1991)

Key Points

- Psychometric theory is predicated on a linkage between constructs and variables, different methods have different assumptions about their relationship
- Variables have multiple sources of relevant variation - construct/trait, method/measurement tool, and idiosyncratic error
- There are many ways to assess construct validity, each with its benefits and drawbacks

Validity assessments

Moving from a summation to tutorial focus

Going forward, our “lecture” period will move away from tying the various papers together and rather using them as a gateway for us to talk about different tools and techniques for performing analyses

Types of validity: Construct-centric

- Criterion validity: The extent to which an operationalization of a construct relates to, or predicts, a theoretically related behaviour or outcome (Cronbach and Meehl 1955, 282) (i.e., semantic relationships and coherence)
- Content or “Face” validity: The extent to which the construct is comprises a sample of a universe in which the investigator is interested (does it look like a duck and quack like a duck?) (i.e., definition and scope conditions) (Cronbach and Meehl 1955)

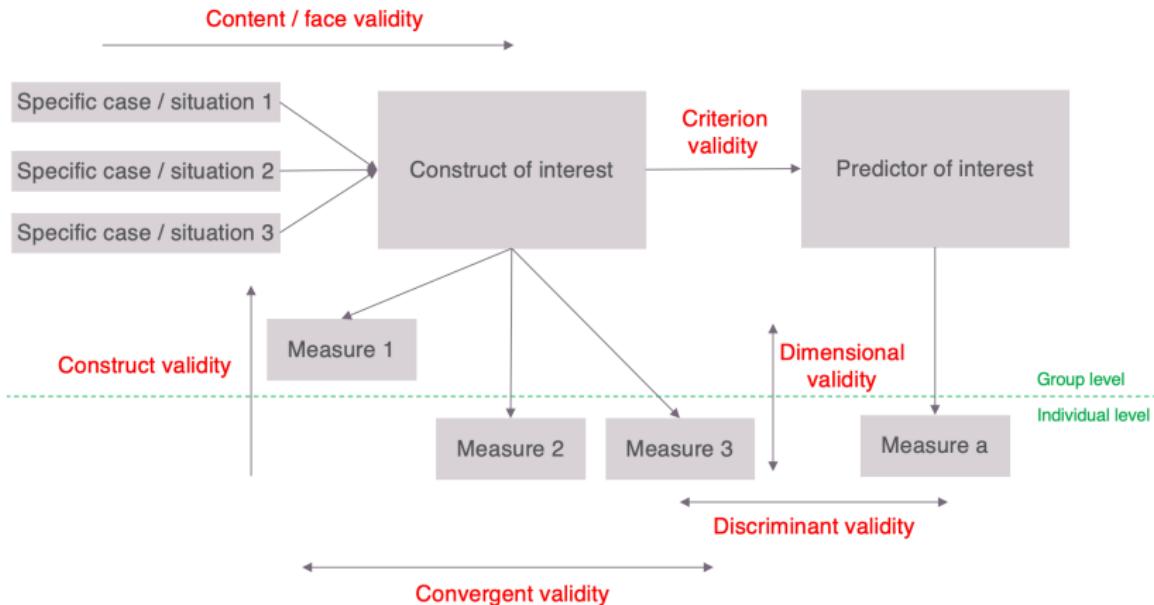

Types of validity: Construct-variable interface

- “Dimensional” validity: The dimension of the constructs and the measures are appropriately specified with due attention paid in operationalization (Law, Wong, and Mobley 1998)
- Construct validity: The extent to which an operationalization measures the concept it is supposed to measure (Bagozzi, Yi, and Phillips 1991, 421)

Types of validity: Variable-centric

- Convergent validity: The degree to which multiple attempts to measure the same concept are in agreement (Bagozzi, Yi, and Phillips 1991, 425)
- Discriminant validity: The extent to which measures of theoretically distinct constructs are unrelated empirically to one another (Campbell & Fiske, 1959) (Shaffer, DeGeest, and Li 2016)

One possible visualization of validity elements

Common tools for assessing validity

- Cronbach's alpha (convergent validity)
 - there are many other "congeneric" tests
- Multi-trait, multi-method matrices (MTMM) (convergent + divergent)
 - this is the canonical approach but relatively inflexible
- Confirmatory factor analyses (convergent + divergent)
 - As (Bagozzi, Yi, and Phillips 1991) notes, there are many versions of this
- A whole bevy of tools for multi-level constructs
 - Some examples include ICC, Rwg, among others

Where does qualitative work fit into all of this?

One interpretation is that qualitative work helps to ascertain the bounds of a construct of interest are and the face validity of any constructs that are subjected to quantitative analyses

Where does actual data fit into all of this?

Where are our measures coming from?

How might data availability enable or constrain the our ability to successfully explore the various elements of the above diagram?
